ELEC3104: Project Outline

- ✓ This mini project (individual) will focus on understanding and modelling the spectral analyses carried out by the human cochlea.

程序代写代做CS编程辅导

- **TLT – Level 1**

Introduction to the Human Auditory System and MATLAB coding fundamentals.

- **TLT – Level 2 (Pass Level)**

Implementation of an **IIR** cochlear filter bank and then conversion to an equivalent parallel **FIR** filter bank model of the cochlea for analysis and synthesis purposes.

- **TLT – Level 3 (Credit Level)**

Using the Level 2 **IIR** cochlear filter bank model, implement a spectral analysis system.

WeChat: cstutorcs

- **TLT – Level 4 (Distinction Level)**

Incorporate temporal masking properties of the cochlea in the **FIR** filter bank model developed in Level 2 and synthesise the signal.

Email: tutorcs@163.com

- **TLT – Level 5 (High Distinction Level)**

Using the Level 2 **FIR** cochlear filter bank model, develop a method for pitch detection of speech signals. Then, use the pitch information to extract a speaker's voice from a mixture of two voices at the input of the filter bank.

Note: In addition to the information provided to you in these slides, you are strongly encouraged to find and view animations and videos that describe the functioning of the peripheral auditory system and the cochlea in particular. Visualisation in the form of these animations will be very helpful in understanding cochlear signal processing.

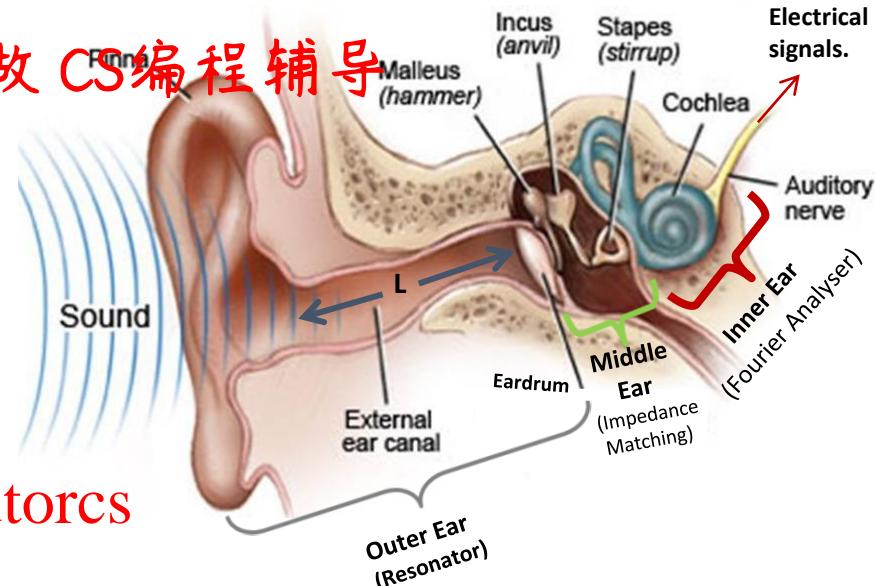

Eg: Cochlear Animation - <https://www.youtube.com/watch?v=dyenMluFaUw>

Introduction to the Human Auditory System

- ✓ The human auditory system is responsible for converting pressure variations caused by the sound waves that reach the ear into nerve impulses that are interpreted by the brain.
- ✓ The Human Auditory System is designed to assess frequency (pitch) and amplitude (loudness).
- ✓ The peripheral auditory system is divided into the Outer Ear, Middle Ear, and Inner Ear.
- ✓ The peripheral auditory system and in particular the cochlea can be viewed as a real-time spectrum analyser.
- ✓ The primary role of the cochlea is to transform the incoming complex sound wave at the eardrum into electrical signals.
- ✓ The human ear can respond to minute pressure variations in the air if they are in the audible frequency range, roughly 20 Hz - 20 kHz

Sounds	Level
Faint	20dB (A faint Whisper is 30dB)
Soft (Quiet)	40dB
Moderate	60dB (normal conversation)
Loud	80dB (alarm clocks, vacuum cleaners)
Very Loud	90dB(Blenders);110dB (Concerts, car horns)
Uncomfortable	120dB (jet planes during take off)
Painful and dangerous	130dB(Jackhammers); 140dB(Gunshots) *Use hearing protection

- ✓ Over 85 dB for extended periods can cause permanent hearing loss
- ✓ Zero decibels (0 dB) represent the absolute threshold of human hearing, below which we cannot hear a sound.

Outer Ear (Air Vibration): A resonator

- ✓ The pinna surround the ear canal and functions as sound wave reflectors and attenuators .
- ✓ The sound waves enter a tube-like structure called ear canal and it serves as a sound amplifier.
- ✓ The sound waves travel through the canal and reach the eardrum and cause it to vibrate
- ✓ The length (L) of the human ear canal is 2.8 cm (and 7 mm in diameter)
- ✓ Speed of sound (c) = 340.3 m/sec ;
- ✓ The resonant frequency (f) of the canal is $\frac{c}{4L}$ = 3,038Hz.
- ✓ The human outer ear is most sensitive at about 3kHz and provides about 20dB (decibels) of gain to the eardrum at around 3000Hz.

<https://tutorcs.com>

Outer ear is a low-Q bandpass filter
(Representative figure only)

Middle Ear: An Impedance Matcher & an Amplifier

- ✓ Middle ear transforms the vibrating motion of the eardrum into motion of the stapes via the two tiny bones, the malleus and incus .
- ✓ The pressure of the sound waves on the oval window is around 25 times higher than on the eardrum.
- ✓ Since the sound Intensity (I) is proportional (\propto) to the square pressure (P^2), the sound intensity increases 625 times (or 28dB)
- ✓ Middle ear converts acoustic energy to mechanical energy and mechanical energy to hydraulic energy

The combined frequency response of the outer and middle ear is a band-pass response, with its peak dominated near 3 kHz

QQ: 749389476

<https://tutorcs.com>

Inner Ear

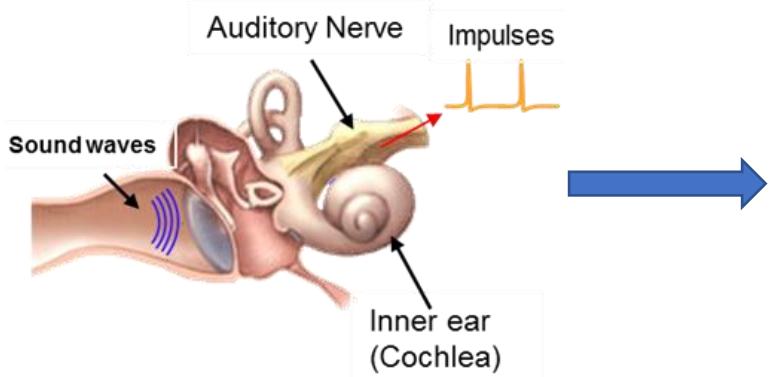

- ✓ The **inner ear** consists of the cochlea responsible for converting the vibrations of sound waves into electrochemical impulses which are passed on to the brain via the auditory nerve.

- ✓ The cochlea is a spiral shaped structure which is about 3.5 cm in length if uncoiled.

- ✓ The cochlea is divided along its length by the **basilar membrane (BM)** which partitions the cochlear into two fluid canals (scala vestibuli and scala tympani).

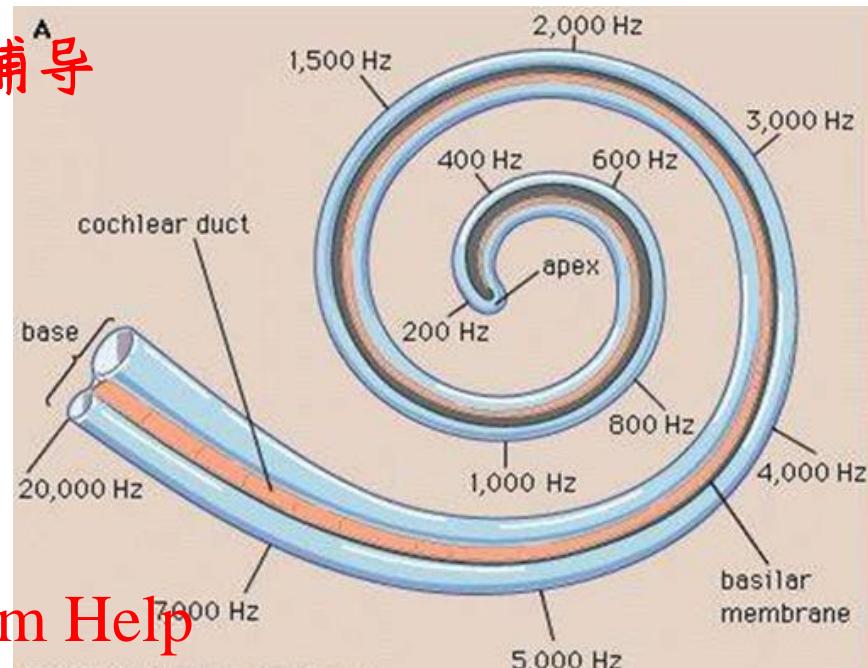

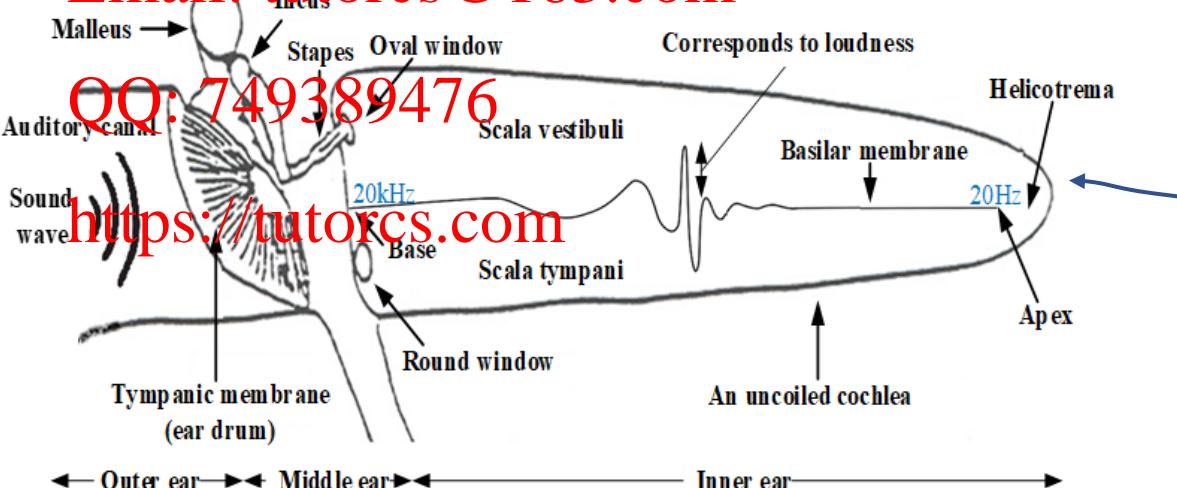

- ✓ The BM terminates just reaching the helicotrema, so there is a passage way between the scala vestibuli and the scala tympani equalising the difference in pressure at the ends of the two scalas.

Assignment Project Exam Help

Email: tutorcs@163.com

Basilar Membrane (Hydro Dynamical process)

- ✓ The Basilar Membrane varies in width and stiffness along its length.
- ✓ At basal end it is narrow and stiff where as towards the apex it is wider and more flexible.
- ✓ Each point along the basilar membrane has a characteristic frequency, $f_p(x)$, to which it is responsive.
- ✓ The maximum membrane displacement occurring at the basal end for high frequencies (20 kHz) and at the apical end for low frequencies (70Hz).
- ✓ When the vibrations of the eardrum are transmitted by the middle ear into movement of the stapes, the resulting pressure differences between the cochlear fluid chambers, generate a travelling wave that propagates down the cochlea and reach maximum amplitude of displacement on the basilar membrane at a particular point before slowing down and decaying rapidly
- ✓ The location of the maximum amplitude of this travelling wave varies with the frequency of the eardrum vibrations

QQ: 749589476

<https://tutorcs.com>

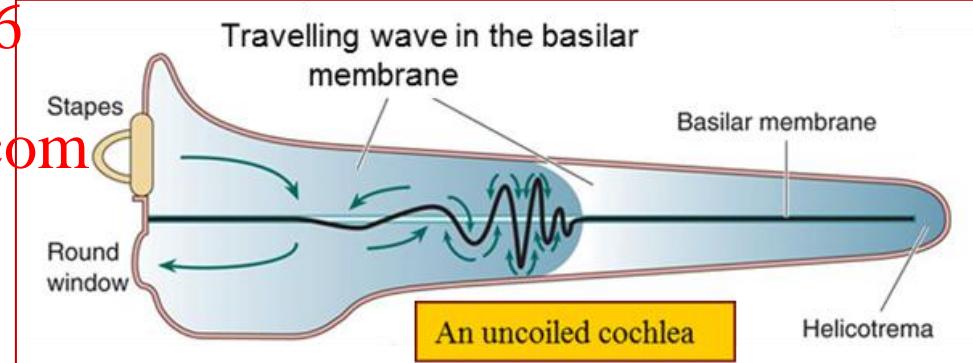

Unrolled basilar membrane

If x is the distance of a point on the basilar membrane from the stapes, then the frequency, $f_p(x)$, that produces a peak at this point is given by:

$$f_p(x) = (20000.0) 10^{-0.667x} \text{ Hz} \quad 0 \leq x \leq 3.5 \text{ cm}$$

- It is evident that a 20 kHz tone at the stapes will cause the BM to vibrate at a point $x = 0$.
- A 70 Hz tone will excite the BM at a point $x = 3.5 \text{ cm}$ (i.e. at the apex)

The basilar membrane is a resonant structure that vibrates, vertically in sympathy with pressure variations in the cochlear fluid.

Basilar Membrane

- ✓ Different frequencies stimulate different areas of the basilar membrane
- ✓ When a tone (single sinusoid) is applied, the cochlear fluid oscillates in phase with the stimulus frequency causing a travelling wave pattern of vibration on the basilar membrane
- ✓ There will be one place where the resonant frequency of the membrane matches the stimulus frequency and this place will show the maximum amount of vibration
- ✓ By measuring vibration at particular points on the basilar membrane for a range of stimulus frequencies we can plot the frequency response of each place on the membrane
- ✓ The essential function of the basilar membrane is to act as a frequency analyser (a set of band-pass filters each responding to a different frequency region) resolving an input sound at the eardrum into its constituent frequencies

Organ of Corti

- ✓ Attached to the basilar membrane and running its entire length is the organ of corti containing some 30,000 sensory hair cells.
- ✓ The hairs (cilia) of these cells stick up from the and are in contact with overlying Tectorial Membrane.
- ✓ There are two types of sensory hair cells:
 - One row of inner hair cells, whose cilia float freely in the fluid-filled region called subtectorial space
 - Three rows of outer hair cells whose cilia are attached to the tectorial membrane
- ✓ Most of the afferent fibres (neurons which carry signals to the brain) come from inner hair cells,
- ✓ The efferent fibres (which receive signals from the brain) go mainly to outer hair cells.
- ✓ When the basilar membrane deflects, due to pressure wave in the cochlear fluid, the tectorial membrane move and shear which causes the hairs of the outer hair cells to bend and also cause the fluid flow in the subtectorial space.
- ✓ This in turn triggers the inner hair cells to transmit nerve impulses along the afferent fibres and eventually to brain.
- ✓ The motion of each part of the basilar membrane as detected by the inner hair cells is transmitted as neural description to the brain.

Organ of Corti

A simplified Diagram of a Human Auditory System

Mechanical to Neural Transduction (Electro Chemical)

- ✓ The mechanical displacement to electrical energy transduction process takes place in the inner hair cells
- ✓ Bending of the inner hair cell cilia due to membrane displacement produces a change in overall resistance (reduces it) of the inner hair cell, thus modulating current flow through the hair cell.
- ✓ The modulation being directly proportional to the degree of bending of the cilia and the bending of the cilia is one direction only; in effect a half wave rectification of the basilar membrane displacement takes place.
- ✓ Bending of the cilia releases neurotransmitter which passes into synapses of one or more nerve cells which fire to indicate vibration
- ✓ The amount of firing is thus related to the amount of vibration
- ✓ Since the neurotransmitter is only released when the cilia are bent in one direction, firing tends to be in phase with basilar membrane movement

Inner Hair Cell model

Here bending the inner hair cell cilia is simulated by charging of the capacitor and returning to the initial position of the cilia is equivalent to discharging the capacitor.

Mechanical to Neural Transduction (Electro Chemical)

- ✓ The model inner hair cell is a capacitor model, in which the input voltage corresponds to the spatially differentiated membrane displacement output of the auditory model. (Second part of Figure below). Here bending the inner hair cell cilia is simulated by charging of the capacitor and returning to the initial state of the cilia is equivalent to discharging the capacitor.
- ✓ Spatial differentiation refers to taking the derivative with respect to position (along the basilar membrane) and a discrete model is given by:

$$\frac{d[i+1] - d[i]}{\Delta x_i}$$

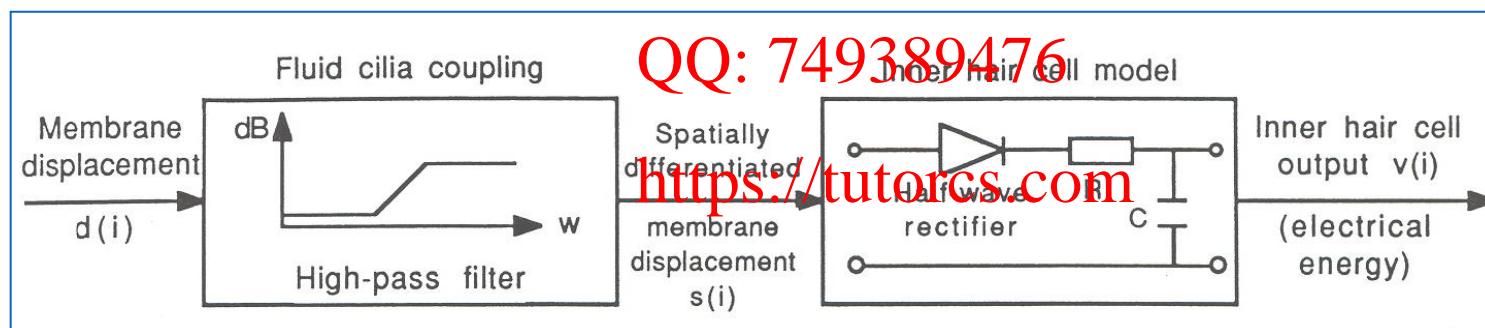

where, $d[i]$ is the displacement at the i^{th} section along the membrane and Δx_i is the width of the i^{th} section

- ✓ Spatial differentiation of the membrane displacement represents coupling between the cilia of the inner hair cells , through the fluid in the subtectorial space (high-pass filter effect, first part of Figure below)
- ✓ You will implement a digital model for neural transduction in **TLT Level 2** in addition to the transmission line auditory model

<https://tutorcs.com>

Learning Activity 1: Modelling the Outer Ear and the Middle Ear

- ✓ The middle ear may be modelled as a cascade of two complex pairs of zeros (to remove very high and very low frequencies) and one complex pair of poles (to provide low-Q gain at the middle frequencies). The approximate frequency response of the middle ear can be seen in the figure below.
Assuming a sampling frequency of 16kHz:

- (a) Obtain the transfer function of the **middle ear** by suitably placing poles and zeros on the z-plane. Verify your results in MATLAB.
- (b) Using placement of poles and zeros, estimate a model for the **outer ear** and cascade it with your previous model of the middle ear and show using MATLAB that the overall response matches the one shown in this figure.

WeChat: cstutorcs

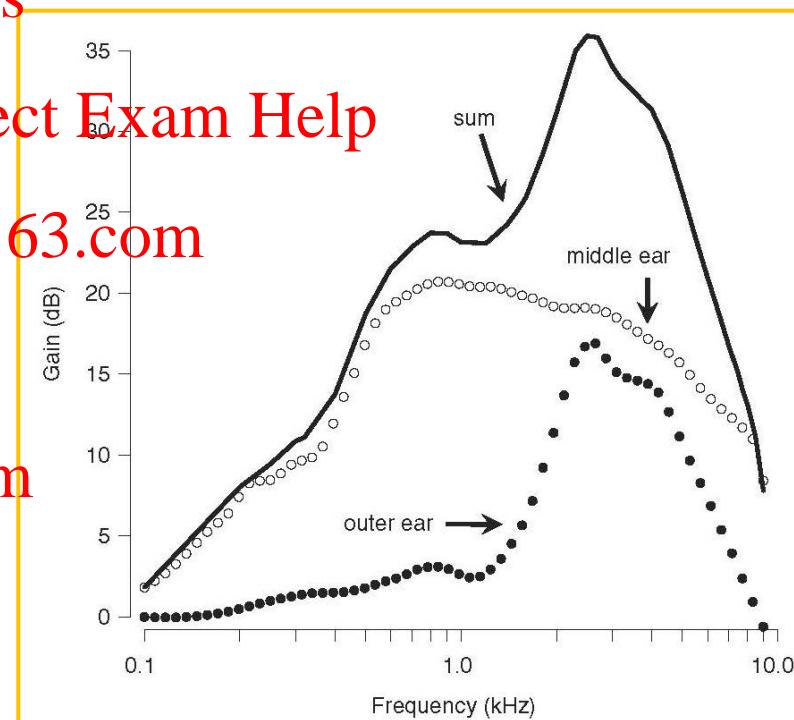

The combined frequency response of the outer and middle ear is a band-pass response (sum = see the adjacent magnitude response diagram), with its peak dominated near 3 kHz

Filter Design: Pole zero placement

- ✓ Calculate the digital filter coefficients of the resonant pole and resonant zeros using pole zero placement (e.g. : see diagram below) 程序代写代做 CS 编程辅导

- ✓ Resonant pole frequency = θ_p ; radius = $r_p = \frac{2\pi f_p}{f_s}$ = 16kHz (or higher)

- ✓ Resonant zero frequency = θ_z ; radius = r_z (closer to unit circle); $\theta_z = \frac{2\pi f_z}{f_s}$

$$\checkmark H_p(z) = \frac{z^2}{(z - r_p e^{j\theta_p})(z - r_p e^{-j\theta_p})} = \frac{z^2 - r_p(e^{j\theta_p} + e^{-j\theta_p})z + r_p^2}{z^2 - r_p(2 \cos \theta_p)z + r_p^2} = \frac{z^2}{1 - 2r_p \cos \theta_p z^{-1} + r_p^2 z^{-2}}$$

- ✓ $H_p(z) = \frac{1}{1 - b_1 z^{-1} + b_2 z^{-2}}$ (from one section of the digital filter) – Equating to above, we obtain

WeChat: cstutorcs **Assignment Project Exam Help**
 $b_1 = 2r_p \cos \theta_p$ and $b_2 = r_p^2$.

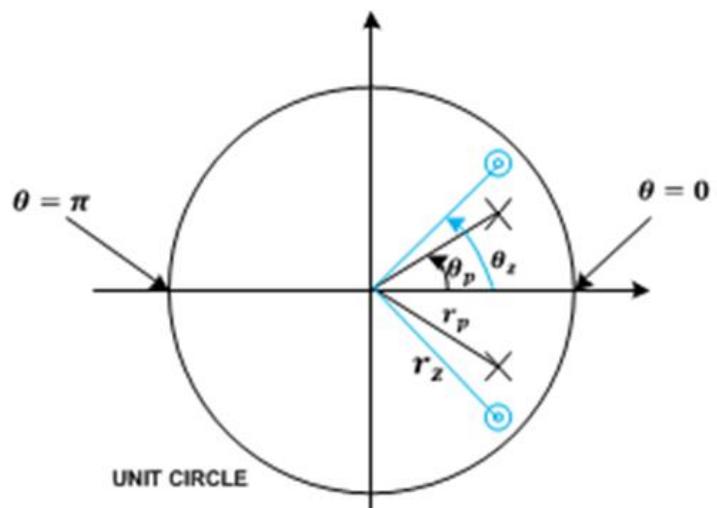

- ✓ Similarly, $a_1 = 2r_z \cos \theta_z$ and $a_2 = r_z^2$ for $H_z(z) = \frac{1 - a_1 z^{-1} + a_2 z^{-2}}{1 - a_1 + a_2}$
- ✓ Both transfer functions can be normalised such that DC gain = 1 as follows:

$$H_p(z) = \frac{1 - b_1 + b_2}{1 - b_1 z^{-1} + b_2 z^{-2}} \text{ and } H_z(z) = \frac{1 - a_1 z^{-1} + a_2 z^{-2}}{1 - a_1 + a_2}$$

- ✓ r_p and r_z can be calculated approximately as follows: <https://tutorcs.com>

$$r_p \approx 1 - \left(\frac{BW_p}{f_s}\right)\pi; r_z \approx 1 - \left(\frac{BW_z}{f_s}\right)\pi$$

$$\text{Q-factors: } Q_p = \frac{f_p}{BW_p}; \quad Q_z = \frac{f_z}{BW_z}$$

Pole – zero plots and magnitude responses of the outer ear

Learning Activity 2 : Impulse and Magnitude Responses

- ✓ The impulse response of an auditory filter can be modelled by:

$$g[n] = k \cdot (nT)^{N-1} e^{-2\pi b(24.7 + 0.168/f_p)nT} \cos(2\pi f_p nT)$$

where, f_p is the centre frequency, T is the sample period ($f_s=1/T$), n is the discrete time sample index, N is the order of the filter ($N = 4$) and a is a constant chosen such that the filter gain at the centre frequency is 0dB ; $b = 1.14$; $f_s = 16,000$ Hz.; [Initially, you may choose $a=1$ and then change it to $a=0.168$ such that the gain of the filter is normalised to 0dB at the centre frequency, f_p .

- ✓ You are required to calculate the impulse responses, $\{g[n]\}$, for four auditory filters of your choice from the low, mid and high frequency regions of the basilar membrane using the equation $\{f_p(x)\}$ given below in MATLAB.

$$f_p(x) = (8000.0) 10^{-0.667x} \text{ Hz} \quad 0.0869 \text{ cm (80 Hz)} \leq x \leq 2.9985 \text{ cm (7 kHz)}$$

You will notice that the impulse responses have infinite duration, and thus each impulse response will need to be truncated to, say, 150 to 200 coefficients (i.e., $0 \leq n < 200$)

Assignment Project Exam Help

- ✓ Plot the impulse responses of all four filters. **Email: tutorcs@163.com**

- ✓ Plot the magnitude responses of all four filters. **QQ: 749389476**

- ✓ Plot the centre frequency, bandwidth and Q factor for all filters. **<https://tutorcs.com>**

Discuss your plots with your lab demonstrator.

Magnitude response of 4 selected filters

Reflections

Reflections

程序代写代做 CS 编程辅导

- (a) What major differences do you see between the impulse responses you have plotted and why?

- (b) Using these impulses responses, find the impulse responses of all four filters and plot them (frequency vs magnitude in dB) on the same figure and compare them.

- (c) The gains at the centre frequencies of the filters may not be equal, choose the scaling factor ' k ' for each filter (see equation of $g[n]$) such that the gain of each filter is normalised to 0dB at the centre frequency.

WeChat: cstutorcs

- (d) Approximately estimate the 3dB bandwidths of all four filters from your plots. Do they vary with the centre frequency? If so, how do you think they are related?

Assignment Project Exam Help

- (e) Explain your understanding of constant-Q filters and constant-Bandwidth filters.
